Today's content

→ Function call tracing

→ Recursion

→ How to write a recursive code?

→ Tracing

→ TC/SC of recursive code } Next class }

Why recursion?

→ Used in Mergesort / Quicksort

→ Binary Tree / BST / Tries

→ Dynamic programming

→ Back tracking

→ Graphs

Function call tracing

```
int add(n, m){  
    return n+m;  
}
```

```
int mul(x, y){  
    return x*y;  
}
```

```
int sub(x, y){  
    return x-y;  
}
```

```
main() {
```

```
    x = 10, y = 20
```

```
    print(sub(mul(add(x, y), 30), 75);
```

825

```
}
```

900

sub(mul(add(x, y), 30), 75) = 825

30

mul(add(x, y), 30) = 900

10, 20

add(x, y) = 30

Stack

Last In
First Out

print(825)

Obs 1 → Whenever we call for function, it gets added at top

Obs 2 → When function returns, function will get removed from the top

Recursion → Repeating code / Re occurring code

→ Function calling itself

→ Solving a problem using a **subproblem**

Q1. Sum of n natural number

$$\text{sum}(n) = 1 + 2 + 3 + \dots + (n-1) + n$$

$$\text{sum}(n) = \underbrace{\text{sum}(n-1)}_{\text{subproblem}} + n$$

$$\text{sum}(4) = \underbrace{1 + 2 + 3}_{\text{sum}(3) + 4} + 4$$

// sum(3) is a subproblem

* Steps to recursive code

01. Assumption/Expectation → Fix what should our function do or what is expected from the function
02. Main logic → Solving assumption using the subproblem
03. Base condition → last valid input for which recursion has to stop

* Sum of n natural numbers ($n > 0$)

// Ass → Given n , calculate & return sum of n natural no.

```
int sum(n) {  
    if (n == 1) return 1;  
    return sum(n-1) + n;  
}
```

Tracing

main()

print (sum(4));

}

return 10

```
int sum(N) n=4
| if (N==1){return 1;}
| return (sum(N-1) + N)
| }
```

6 + 4

```
int sum(N) n=3
| if (N==1){return 1;}
| return (sum(N-1) + N)
| }
```

3 + 3

```
int sum(N) n=2
| if (N==1){return 1;}
| return (sum(N-1) + N)
| }
```

1 + 2 = 3

```
int sum(N) n=1
| if (N==1){return 1;}
| return (sum(N-1) + N)
| }
```

return 3

return 1

Without base condition

↘
Recursion will never stop

(a) TLE $\longrightarrow$ X

(b) Memory Limit Exceeded / Stack overflow

Note :- Limit to function calls $\approx 10^5$

Note :- If code is giving stack overflow,
check for base condition

Q1. Can we write the base condition below recursive call?

First thing to write is base case

02. Factorial of a number ($n \geq 0$)

$$\text{fact}(3) = 3 * 2 * 1 = 6$$

$$\text{fact}(4) = 4 * 3 * 2 * 1 = 24$$

$$\text{fact}(n) = n * (n-1) * (n-2) * \dots * 3 * 2 * 1$$

$$\text{fact}(4) = 4 * \text{fact}(3)$$

// Expectation $\rightarrow$ Given n , calculate & return $n!$

```
int fact(n)
```

```
    | if (n == 0) return 1;  
    | return n * fact(n-1);  
    |  
    }
```

$$0! = 1$$

Tracing $\rightarrow$ {TODO}

fibonacci number ($N \geq 0$)

# Input	0	1	2	3	4	5	6	7	8
Fib()	0	1	1	2	3	5	8	13	21

$\text{fib}() = \text{sum of previous two fibonacci no.}$

Subproblem $\text{fib}(n)$

$$\text{fib}(7) = \text{fib}(6) + \text{fib}(5)$$

$$\text{fib}(80) = \text{fib}(79) + \text{fib}(78)$$

$$\text{fib}(n) = \text{fib}(n-1) + \text{fib}(n-2)$$

// Assumption $\rightarrow$ Calculate & return n^{th} fib number

```
int fib(n)
|
|  if (n ≤ 1) return n;
|
|  return fib(n-1) + fib(n-2);
|
}
```

Note :- Figure out the base case

↳ For what valid input, the main logic should not run

$$\text{fib}(0) = \text{fib}(0-1) + \text{fib}(0-2)$$

Invalid

$$\text{fib}(1) = \text{fib}(1-1) + \text{fib}(1-2)$$

Invalid

Invalid, base condition for these two state

$$\text{fib}(2) = \text{fib}(2-1) + \text{fib}(2-2)$$

→ return 3 to main()

03. Given n , print all the numbers from 1 to N .
in increasing order [$n > 0$]

Inc (3) $\rightarrow$ 1 2 3

Inc (4) $\rightarrow$ 1 2 3 4
Inc (3) 4

// Assumption $\rightarrow$ Given n , print all the no. from 1 to n

```
void inc(n)
{
    if (n == 1) {
        print(1);
        return;
    }
    inc(n-1);
    print(n);
}
```

* Base condition

Base case
 $\hookrightarrow$ The last valid input for which your main logic fail

Note:- Return statement means, the task of the function is complete, go back to your caller

Note:- Always return back from base case

void inc(n) $n=4$

if (n==1) { Print(1);
 return }

inc(n-1)

print(n)

void inc(n) $n=3$

if (n==1) { Print(1);
 return }

inc(n-1)

print(n)

void inc(n) $n=2$

if (n==1) { Print(1);
 return }

inc(n-1)

print(n)

void inc(n) $n=1$

if (n==1) { Print(1);
 return }

inc(n-1)

print(n)

return;

Output

1

2

3

4

Write the code

```
if (n > 1) {
    inc(n-1)
    print(n)
}
```

TODO → { Write a function which prints the number in decreasing order

$n=4$ Output $\rightarrow$ 4 3 2 1

$n = 5$ output $\rightarrow 5 \ 4 \ 3 \ 2 \ 1$

05. Given a `ch[]`, check if the given `ch[]` is palindrome for indexes $[s < e]$

ch[] = { a m a z o n } s=2
 0 1 2 3 4 5 e=4

↓
False

ch [] = { m a d a m } s = 1
 0 1 2 3 4 e = 3

True

ch [] = { m a d a m } s = 0
 0 1 2 3 4 e = 4

True

Assumption $\rightarrow$ Return if the ch array from $s \rightarrow e$ is a palindrome or not

ch[] = s s+1 s+2 e-2 e-1 e

Ex:- m a l y l a m $\rightarrow$ True

Diagram illustrating the recursive step for the word "madam":

- The word "madam" is shown with a green bracket above it, indicating the full word.
- The word is split into "ma" (left) and "dam" (right).
- The recursive call for "ma" is shown as $\text{is_palindrome}(\text{"ma"})$, which returns False .
- The recursive call for "dam" is shown as $\text{is_palindrome}(\text{"dam"})$, which returns False .
- The overall result for "madam" is False , indicated by a red arrow.

To return True $\rightarrow$ (s) & (e) must be same

and the inner part must also

be saying that i'm palindrom

```
boolean ispal ( ch[], int s, int e )
```

```
    if (s > e) return true;
```

```
    if (ch[s] == ch[e] && ispal (ch, s+1, e-1) == true)
```

```
        return true;
```

```
    }
```

```
    return false;
```

```
}
```

```
main ( ) {
```

```
    ch[] = { n o o n }
```

```
    s = 0
```

```
    e = 3
```

```
    print ( ispal (ch, s, e) );
```

```
}
```

```
boolean isPali (ch, s, e)
```

```
    if (s > e) return true;
```

```
    if (ch[s] == ch[e] &&
```

```
        isPali (ch, s+1, e-1))
```

```
        return true
```

```
    return false
```

s = 0

e = 3

True

```
boolean isPali (ch, s, e)
```

```
    if (s > e) return true;
```

```
    if (ch[s] == ch[e] &&
```

```
        isPali (ch, s+1, e-1))
```

```
        return true
```

```
    return false
```

s = 1

e = 2

return
True

```
boolean isPali (ch, s, e)
```

```
    if (s > e) return true;
```

```
    if (ch[s] == ch[e] &&
```

s = 2

e = 1

```

    }
    }
    return false
}

```

— x — x — x — x — x —

$[s < e]$

$s = 0 \quad e = 0$ x

if (C_1 fails or C_2 fails)

return false
